Introduction		• •	• •	• •	• •	٠
Setup						
Database (neo4	j)					
Jersey						
Performance						

We are a team of 5 students from the University of Bern. In the course of the ?Practical Software Engineering? lecture we have been assigned this digital humanities software development project. The goal of this lecture is to experience the development process of a software while working in a team.

The development process included the collection of the requirements through interviews with the customer, implementing the user-stories using agile programming techniques, constant dialog with the customer to ensure the software fulfils her requirements and finally delivering the project to the costumer so it can be put into use.

Our customer?s goal is to create a tool to analyse old texts by comparing different versions of them. The prototype of this web tool, StemmaWeb, focused on functionality and not on performance, which led to very slow loading times due to the complexity of the different connections between elements in different texts. We were asked to evaluate and develop a more efficient system which should drastically improve StemmaWeb ?s performance, purposely by using a graph database over a standard relational database.

To achieve this we used the graph database Neo4. We programmed the software in the programming language Java and worked with Jersey, a Java RESTful framework. In four iterations during 12 weeks we implemented the user-stories given to us and defined a unique API call for each implemented function. This will allow the customer to easily connect her existing Graphical User Interface to the new software we have created.

# **Downloading**

git clone https://github.com/tohotforice/PSE2\_DH.git

### Building

Stemmarest needs to be built using Maven. This can be done using a java IDE (e.g Eclipse) and a Maven plugin

## Running

As this application represents a server side only, there is no full GUI included. It is possible though to test it by using the test interface testGui.html which is located at StemmaClient.

### Using the test interface

- Create a user and give it an id (this is necessary as every graph needs to be owned by a user)
- Import an GraphML file using the id of the user you have created. The generated id of the tradition will be returned
- Use the custom request by typing in the API call you want (all calls are listed in the documentation)

A word about node id's: when a graph is being imported each node gets from Neo4j a unique id-number. In order to use an id in an API call (e.g. reading-id) it is necessary to explicitly get it from the data base. This can be done by using the getAllReadings method (getallreadings/from-tradition/traditionId) or by actually going into the data base (see Neo4j visualization in section Database)

In this project a graph database is used to store the data.

This was done as graph databases are much faster when it comes down to look for objects in a list that contain some constraints to other objects. In a relational database one would normally use multiple joins to get the desired result, but by using a graph this task becomes much easier since it is possible to traverse the graph from node to node using either breadth- or depth-first algorithm and to for a specific relation between two nodes, which represent objects. This method makes a search for objects, which are connected to each other, very efficient.

We chose to use Neo4J (more information can be found at http://neo4j.com/developer/graph-db-vs-rdbms/) which is a graph database capable of very efficiently managing nodes and relationship even in a large scale graph.

Additional information regarding performance could be found in the related chapter of this documentation.

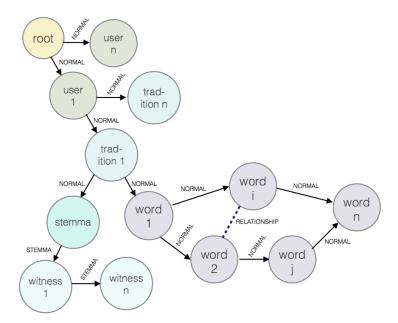

The stemmaweb database is basically a one big graph, with different labels marking different nodes and relationships.

Only a few labels are used in the database:

Nodes	Relationships
ROOT	RELATIONSHIP
STEMMA	STEMMA
WITNESS	NORMAL
TRADITION	
USER	
WORD	

Since each label is stored in another file, searching or traversing the graph is stunningly fast.

The database structure is as follows:

Neo4J uses a powerful script language called cypher. Cypher is a declarative graph query language that allows for expressive and efficient querying and updating of the graph store. Using cypher one can write simple queries that return nodes or traverse graphs. Cypher queries, though, need to be interpreted and translated into an execution plan and that is why they are still less fast then the native java traversal API which has become the common query tool used in the project.

### Introduction

Jersey is an open source java framework for developing RESTful Web Services in Java that is built upon JAX-RS and serves as a JAX-RS Reference Implementation. It adds additional features and utilities in order to further simplify development of REST-APIs. Jersey helps support exposing the data in different media types, including JSON, which is very frequently used in this program.

#### **Method Declarations**

An example of the method declaration of duplicateReading in the reading class:

```
@POST
@Path("duplicatereading")
@Consumes(MediaType.APPLICATION_JSON)
@Produces(MediaType.APPLICATION_JSON)
public Response duplicateReading(DuplicateModel duplicateModel)
```

The @POST annotation states the http method. The @Path annotation sets the url path. The method "consumes" (i.e. gets from the client side) data sent by the client, in this case a java object of a "DuplicateModel" which is passed with the call as a JSON object and then gets parsed by the server into a POJO. The method "produces" (returns) a response, which is the method's return value, in this case also in JSON.

And here another example from the witness class:

The values in curly braces in the path (tradId and witnessId) are path parameters, which are used in the method. In the method declaration they are annotated with @PathParam.

#### **Resources**

In the ApplicationConfig class all the IResources (the objects) are loaded in the following method:

```
@ Override
public Set < Class <?>> get Classes() {
    Set < Class <?>> s = new HashSet < Class <?>>();
    s.add(Witness.class);
    s.add(User.class);
    s.add(Tradition.class);
    s.add(Relation.class);
    s.add(Stemma.class);
    s.add(Reading.class);
}
```

An 'IResource' is a class that provides methods annotated with @GET, @POST, @PUT or @DELETE. All the API calls that can be made using stemmarest are defined in those six classes: Witness, User, Tradition, Relation, Stemma and Reading.

```
@Path("/reading")
public class Reading implements IResource {
```

All of those classes implement the IResource interface. Additionally the path of the database is set in this interface. This a path can also be set for an entire class which means that it is set before each method of this class. So duplicateReading, for example, can be reached under "baseurl/reading/duplicatereading".

One of the main goals of this project was to create a RESTful service which is significantly faster then the existing one. To verify the speed of the service some performance tests are done.

The goal of the performance tests is to show that the response time of the service is limited and within a usable range and so those tests measure the time to execute all operations for a certain request. This includes the time to transmit the data over HTTP, the time to execute the internal algorithms and the time to access the database. All the Data is transmitted over the local loop interface. The network speed is therefore not measured.

For the purpose of the tests the database is being populated by a random graph which contains several valid traditions on which the REST requests can be executed. Several tests with databases of different sizes are done to show that the response time does not change as the size of the database increases.

The following measurements show the result of tests which test the dimension of the database. Those tests show that the RESTful service response time is not influenced by the size of the database in a significant way. This is related to the use of the Graphdatabase in which a query can search a subgraph without filtering the whole database.

The implementation of stemmarest uses some search-node-by-id methods (a part of Neo4j framework) which search over the complete database. It is important to realize that those quarries are done in O(logn) time and are not seen in the noise of the other operations during the tests. In a much bigger Database those methods will slow down the REST requests, though it is not expected that the database will grow so big that such operations will have any impact.

The previous measurement show the dimension of the database and could show that the response time is almost independent to its size between 1000 and 1 Million Nodes (Readings). This is a results of the fact that each Tradition can be selected as a subgraph and the algorithms only have a subset of the whole database to search trough. It is obvious the tradition size have an influence on

the speed of the implemented algorithms as the working subset grows with a bigger tradition. Most of the algorithms which work on a tradition are in O(logn), though there are also some export and

import functions which have to handle each node and relation of the tradition and run in O(n).

In the following tests the dimension of the tradition is varied while the size of the database stays the same. Those measurements show that the execution time depends on the size of the

working tradition, as can be seen in the results for the getAllReadingsFromATradition method, in which each reading of the tradition is parsed to a JSON Object and all are returned as an List. The parsing of those nodes executes in O(n) time and the downloading of the JSON file takes about the same. As larger traditions are not expected the execution time of those methods stays in the accepted range.

	Concept
,	Configure the Test-Database
3	Integration Tests
)	Benchmark Testing

This chapter describes the test-concept of the Project. The testing were used for test driven development and to assure the quality of the project. All tests are written in such a manner that they do not have any impact on the architecture of the project.

# **Integration Tests**

Every user story is tested with integration tests. Those tests are the mean of assuring the quality of the project. The technique of integration tests is described in the Integration test chapter.

# **Jersey Overview**

For every REST call in the system a jersey instantiate the requested IResource and provides the service. A global singleton GraphDatabaseService object, which is is an embedded neo4j GraphDatabase, is used to provide the service. To achieve a minimal invasive test system the productive database is being replaced with a test database. To change the database with minimal test related code in the project, the GraphDatabaseServiceProvider is configured to return an impermanent Database. As the GraphDatabaseService is a singleton object this configuration is done before the start-up of the Jersey Testserver.

To use a Testdatabase in the Tests the following steps are done: A Claswide GraphDatabaseService object db is registered.

GraphDatabaseService db;

In the @Before method the singleton GraphDatabaseService provided by the GraphDatabaseServiceProvider is overwritten by the following line:

Graph Database Service Provider . set Impermanent Database (); Later the db object is initialized by:

```
db = new GraphDatabaseServiceProvider().getDatabase();
```

In the @After method the database is being closed

```
db.shutdown();
```

With this configuration the impermanent Testdatabase of Neo4j is used during the tests.

To inject objects into a resource the resource must be created statically. This is not possible when the resources are instantiated when a REST call occurs. To solve this problem JerseyTest-ServerFactory creates a server where already instantiated resources can be registered. To start a JerseyTestServer a global JerseyTest is created.

```
private JerseyTest jerseyTest;
```

The JerseyTestServerFactory creates a JerseyTest with already instantiated resources. This is used to inject the mock objects. Multiple resources can be added by chaining .addResource(..).addResource()

The test is done by calling a webresource of jerseyTest

@Test

```
public void SimpleTest(){
   String actualResponse = jerseyTest.resource()
        .path("/user").get(String.class);
   assertEquals(actualResponse, "User!");
}
```

# Example

The main goal of the stemmarest project was to achieve better performance then the previous service. To measure the performance of the system benchmark testing was needed. A benchmark test basically calls the RESTful service multiple times and measure the response time. To achieve this *com.carrotsearch.junitbenchmarks* a JUnit benchmark test suite is used. The JUnitbenchmarks measures the time which is used to execute a test and can generate visual representations of the measurement.

For effective benchmark testing it is important to have a variety of different databases. Those databases should differ in size from small to very huge. This allows to measure the algorithms in different situations. To generate valid graphs only limited by space the class *RandomGraphGenerator* can be used. By calling this static method a graph is generated according to the given parameters.

Please note that the response time depends highly on the hardware the tests are running on and the actual state of Javas virtual machine.

To reduce the influence of the virtual machine before the measurements 5 warm-up calls are done. The hardware which was used for testing is represented in the report.

### Setup

All the classes related to the Benchmark Tests can be found in the package *net.stemmaweb.stemmaserver.benachmarktests*. The class BenchmarkTests contains all the Tests. The classes Benchmark<n>Nodes contain the database generator. In it the number of nodes in the current test-database is being configured. BenchmarkTests cant be run as a JUnit test.

Tests are implemented in the BenchmarkTests class with the @Test annotation. Only restcall in implement the in the methods and they only test if Response.Status is OK. This assures that as low as possible overhead time will be generated and measured.

JUnitBenchmarks measures the time to execute (@Before, @Test, @After). Heavy operations which should not be measured can be done in @BeforeClass and @AfterClass.

To create a new database, the test-environment copies the class Benchmark600Nodes and rename it to the count of Nodes that are being inserted. In the class itself only two small adjustments are done. First: the name of the report file is being changed @BenchmarkMethodChart(filePrefix = "benchmark/benchmark-600Nodes"). Second: the properties of the database which should be generated are being adjusted rgg.role(db, 2, 1, 3, 100);. role(databaseService, cardinalityOfUsers, cardinalityOfTraditionsPerUser, cardinalityOfWitnessesPerTradition, degreeOfTheTraditionGraphs)

### **Run Benchmarktests**

The Benchmarktests can be run as every JUnit test. To generate the report, though, an argument needs to be passed. Create a JUnit Test as follows:

On the tab Arguments -Djub.consumers=CONSOLE,H2 -Djub.db.file=.benchmarks has to be inserted into the VM Arguments input. After that the test can be run as usual. After the execution of the tests the reports will be stored at benchmark/.

The execution of the tests will take some time because of the need to generate huge graphs. Its recommended not to use the computer for other assignments during the tests.

http://localhost:8080/

# 10.2 /stemma

Method Name: getAllStemmata

Gets a list of all Stemmata available, as dot format

### **GET** /getallstemmata/fromtradition/{tradId}

- **Response** list of stemmata as dot
- Parameter tradId as string

Method Name: setStemma

Puts the Stemma of a DOT file in the database

### POST /newstemma/intradition/{tradId}

- Request as application/json
- **Response** stemma as dot
- Parameter tradId as string

Method Name: reorientStemma

Reorients a stemma tree with a given new root node

POST /reorientstemma/fromtradition/{tradId}/withtitle/{stemmaTitle}/withnewrootnode/{nodeId}

- **Response** stemma as dot
- Parameter tradId as string
- **Parameter** stemmaTitle as string
- Parameter nodeId as string

Method Name: getStemma

Returns JSON string with a Stemma of a tradition in DOT format

**GET** /getstemma/fromtradition/{tradId}/withtitle/{stemmaTitle}

- **Response** stemma as dot
- Parameter tradId as string
- Parameter stemmaTitle as string

#### 10.3 /relation

Method Name: delete

Remove all relationships, as it is done in https://github.com/tla/stemmaweb/blob/master/lib/stemmaweb/Controller/Relatione 271) in Relationships of type RELATIONSHIP between the two nodes.

**POST** /deleterelationship/fromtradition/{tradId}

- **Request** relationshipModel as application/json
- **Response** as text/plain: HTTP Response 404 when no node was found, 200 When relationships where removed
- Parameter tradId as string

Method Name: create

Creates a new relationship between the two nodes specified.

**POST** /createrelationship

- Request relationshipModel as application/json
- Response as application/json

Method Name: getAllRelationships

Get a list of all relationships from a given tradition.

10.4 /tradition 27

### **GET** /getallrelationships/fromtradition/{tradId}

- **Response** list of relationshipModel as application/json
- Parameter tradId as string

**Method Name:** deleteById Removes a relationship by ID.

### **DELETE** /deleterelationshipbyid/withrelationship/{relationshipId}

- **Response** relationshipModel as application/json
- Parameter relationshipId as string

#### 10.4 /tradition

Method Name: getAllRelationships

Gets a list of all relationships of a tradition with the given id.

#### **GET** /getallrelationships/fromtradition/{tradId}

- **Response** list of relationshipModel as application/json
- Parameter tradId as string

**Method Name:** changeTraditionMetadata Changes the metadata of the tradition.

### **POST** /changemetadata/fromtradition/{tradId}

- **Request** traditionModel as application/json
- **Response** traditionModel as application/json
- Parameter tradId as string

Method Name: getAllTraditions

Gets a list of all the complete traditions in the database.

### **GET** /getalltraditions

**Response** list of traditionModels as application/json

Method Name: getAllWitnesses

Gets a list of all the witnesses of a tradition with the given id.

### **GET** /getallwitnesses/fromtradition/{tradId}

- **Response** list of witnessModels as application/json
- Parameter tradId as string

**Method Name:** getTradition

Returns GraphML file from specified tradition owned by user

### **GET** /gettradition/withid/{tradId}

- Response as application/json: XML data
- Parameter tradId as string

**Method Name:** deleteTraditionById Removes a complete tradition

#### **DELETE** /deletetradition/withid/{tradId}

- **Response** as text/plain: http response
- Parameter tradId as string

Method Name: importGraphMl

Imports a tradition by given GraphML file and meta data

### POST //newtraditionwithgraphml

- Request as multipart/form-data
- **Response** the id of the imported tradition as text/plain

Method Name: getDot

Returns DOT file from specified tradition owned by user

### **GET** /getdot/fromtradition/{tradId}

- **Response** as application/json: XML data
- Parameter tradId as string

# 10.5 /reading

Method Name: changeReadingProperties

Changes properties of a reading according to its keys

10.5 /reading 29

### **POST** /changeproperties/ofreading/{readId}

- Request as application/json
- **Response** readingModel as application/json
- Parameter readId as long

Method Name: getReading

Returns a single reading by global neo4j id

#### **GET** /getreading/withreadingid/{readId}

- **Response** readingModel as application/json
- Parameter readId as long

Method Name: duplicateReading

Duplicates a reading in a specific tradition. Opposite of merge

### **POST** /duplicatereading

- Request duplicateModel as application/json
- **Response** GraphModel as application/json

Method Name: mergeReadings

Merges two readings into one single reading in a specific tradition. Opposite of duplicate

### POST /mergereadings/first/{firstReadId}/second/{secondReadId}

- **Response** as application/json: Status.OK on success or Status.INTERNAL\_SERVER\_ERROR with a detailed message.
- Parameter secondReadId as long
- Parameter firstReadId as long

Method Name: splitReading

Splits up a single reading into several ones in a specific tradition. Opposite of compress

#### **POST** /splitreading/ofreading/{readId}/withsplitindex/{splitIndex}

- **Request** as text/plain
- **Response** GraphModel as application/json

- Parameter readId as long
- Parameter splitIndex as int

Method Name: getNextReadingInWitness

gets the next readings from a given readings in the same witness

### **GET** /getnextreading/fromwitness/{witnessId}/ofreading/{readId}

- **Response** readingModel as application/json
- Parameter readId as long
- **Parameter** witnessId as string

**Method Name:** getPreviousReadingInWitness

gets the previous readings from a given readings in the same witness

### GET /getpreviousreading/fromwitness/{witnessId}/ofreading/{readId}

- **Response** readingModel as application/json
- Parameter readId as long
- Parameter witnessId as string

Method Name: getAllReadings

Returns a list of all readings in a tradition

#### **GET** /getallreadings/fromtradition/{tradId}

- **Response** list of readingModels as application/json
- Parameter tradId as string

Method Name: getIdenticalReadings

Get all readings which have the same text and the same rank between given ranks

### GET /getidenticalreadings/fromtradition/{tradId}/fromstartrank/{startRank}/toendrank/{endRank}

- **Response** list of list of readingModels as application/json
- Parameter endRank as long
- Parameter tradId as string
- Parameter startRank as long

Method Name: getCouldBeIdenticalReadings

Returns a list of a list of reading Models with could be one the same rank without problems

10.6 /witness 31

GET /couldbeidenticalreadings/fromtradition/{tradId}/fromstartrank/{startRank}/toendrank/{endRank}

- **Response** list of readingModels as application/json
- Parameter endRank as long
- Parameter tradId as string
- Parameter startRank as long

Method Name: compressReadings

Compress two readings into one. Texts will be concatenated together (with or without a space or extra text. The reading with the lower rank will be given first. Opposite of split

**POST** /compressreadings/read1id/{read1Id}/read2id/{read2Id}/concatenate/{con}

- **Request** as text/plain
- **Response** as application/json: status.ok if compress was successful. Status.INTERNAL\_SERVER\_ERROR with a detailed message if not concatenated
- Parameter read1Id as long
- Parameter read2Id as long
- Parameter con as string

#### 10.6 /witness

Method Name: getWitnessAsText

finds a witness in the database and returns it as a string

**GET** /gettext/fromtradition/{tradId}/ofwitness/{witnessId}

- **Response** a witness as a string
- Parameter tradId as string
- Parameter witnessId as string

Method Name: getWitnessAsTextBetweenRanks

find a requested witness in the data base and return it as a string according to define start and end readings (including the readings in those ranks). if end-rank is too high or start-rank too low will return till the end/from the start of the witness

GET /gettext/fromtradition/{tradId}/ofwitness/{witnessId}/fromstartrank/{startRank}/toendrank/{endRank}

- **Response** a witness as a string
- Parameter endRank as string
- Parameter tradId as string
- Parameter startRank as string
- Parameter witnessId as string

Method Name: getWitnessAsReadings

finds a witness in the database and returns it as a list of readings

### GET /getreadinglist/fromtradition/{tradId}/ofwitness/{witnessId}

- **Response** list of readingModels as application/json
- Parameter tradId as string
- Parameter witnessId as string

### 10.7 /user

Method Name: create

Creates a user based on the parameters submitted in JSON.

### **POST** /createuser

- **Request** userModel as application/json
- **Response** userModel as application/json

Method Name: getUserById

Gets a user by the id.

## **GET** /getuser/withid/{userId}

- **Response** userModel as application/json
- Parameter userId as string

**Method Name:** deleteUserById Removes a user and all his traditions

### **DELETE** /deleteuser/withid/{userId}

Response as text/plain: OK on success or an ERROR in JSON format

10.7 /user 33

Parameter userId as string

Method Name: getTraditionsByUserId

Get all Traditions of a user

# **GET** /gettraditions/ofuser/{userId}

**Response** as application/json: OK on success or an ERROR in JSON format

Parameter userId as string

# 11.1 relationshipModel

- **Property** a\_derivable\_from\_b as string
- Property alters\_meaning as string
- Property annotation as string
- **Property** b\_derivable\_from\_a as string
- Property displayform as string
- Property extra as string
- **Property** id as string
- Property is\_significant as string
- Property non\_independent as string
- Property reading\_a as string
- Property reading\_b as string
- **Property** scope as string
- Property source as string
- **Property** target as string
- Property type as string

**Property** witness as string

# 11.2 readingModel

- **Property** grammar\_invalid as string
- **Property** id as string
- Property is\_common as string
- Property is\_end as string
- Property is\_lacuna as string
- **Property** is\_lemma as string
- **Property** is\_nonsense as string
- **Property** is\_ph as string
- **Property** is\_start as string
- **Property** join\_next as string
- Property join\_prior as string
- Property language as string
- Property lexemes as string
- Property normal\_form as string
- Property rank as long
- Property text as string

### 11.3 traditionModel

- Property id as string
- **Property** is Public as string
- Property language as string
- Property name as string
- **Property** ownerId as string

# 11.4 duplicateModel

- Property readings as long
- **Property** witnesses as string

# 11.5 graphModel

- Property readings as long
- Property witnesses as string

# 11.6 witnessModel

Property id as string

## 11.7 userModel

- Property id as string
- Property is Admin as string

### 11.8 stemma

A tree that provides an overview over the witnesses of a tradition. The relations between the witnesses which are displayed as nodes is central. Here the stemmata are mostly returned in dot format
